There are several ways to formulate a virial series, differing in choice of dependent and independent variables

Most common choices are the activity (z) series (coefficients b_n), and the density (ρ) series (B_n)

$$P(z) = kT \sum_{n=1}^{\infty} b_n z^n$$

$$P(\rho) = kT \sum_{n=1}^{\infty} B_n \rho^n$$

To simplify formulas, we will omit T dependence

We'll consider two models in this presentation

Hard rods in 1D

Lennard-Jones in 3D

We'd like to understand the limits on the VEOS convergence

Density series strictly fails at and beyond spinodal/binodal

$$\sum_k k B_k \rho^{k-1} > 1$$

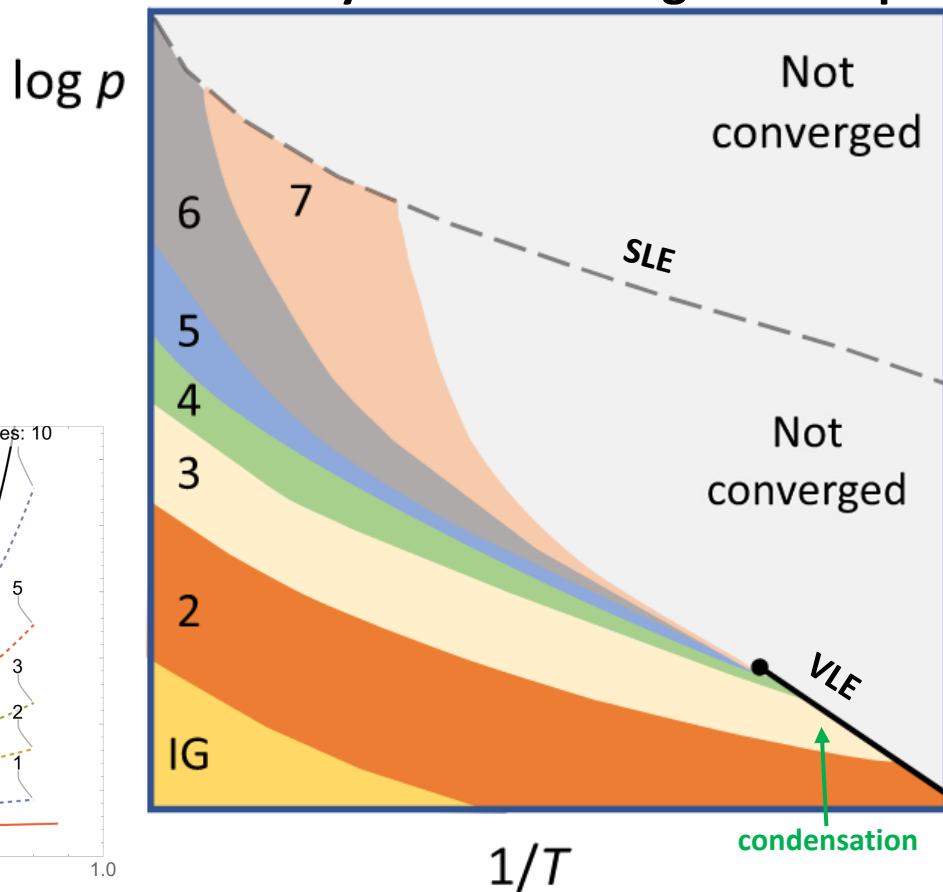

Difficulty converging beyond the Widom line

Activity series $P(z)$ in general is worse

Hard-rod model

Density VEOS Convergence Map

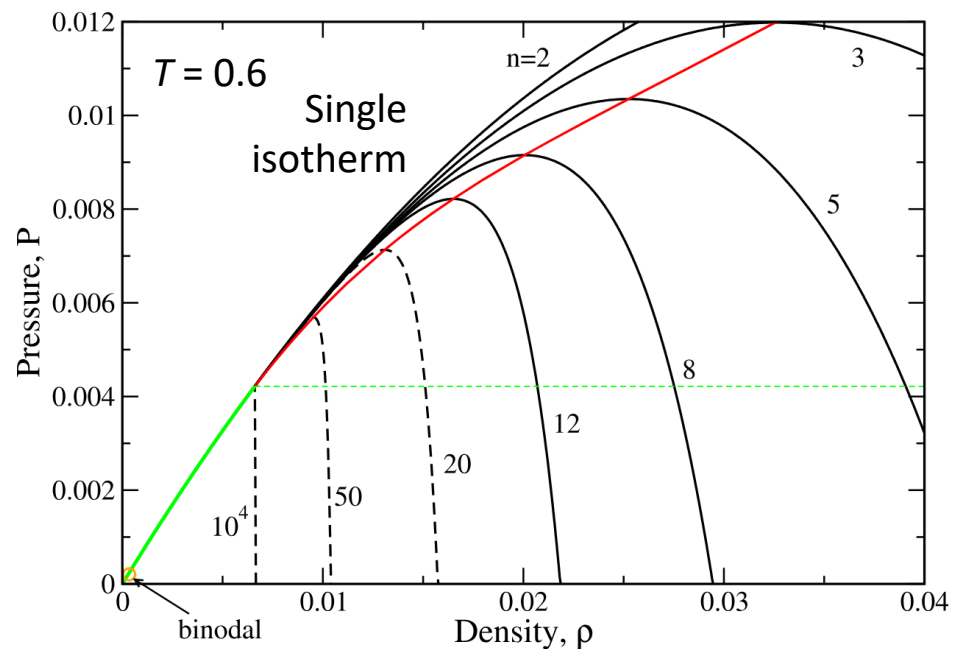

For molecular (rather than thermodynamic) models, the VEOS doesn't have a spinodal

vdW EOS

Lennard-Jones model

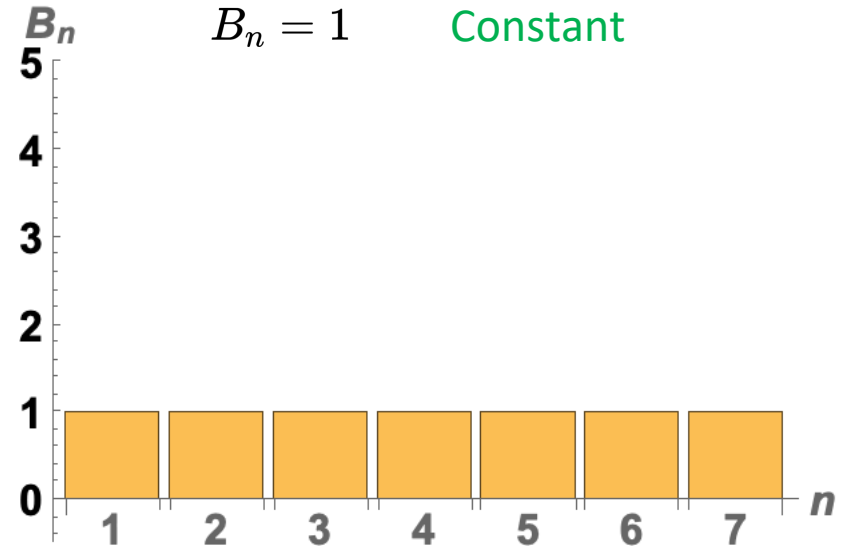

Activity-series and density-series coefficients are very different

1D Hard-rod model

Activity series

Density series

Activity-series and density-series coefficients are very different

3D Lennard-Jones, low temperature ($T = 0.8$)

Activity series

All positive, growing exponentially

Density series

All negative, growing exponentially

Activity-series and density-series coefficients are very different

3D Lennard-Jones, low temperature ($T = 0.8$)

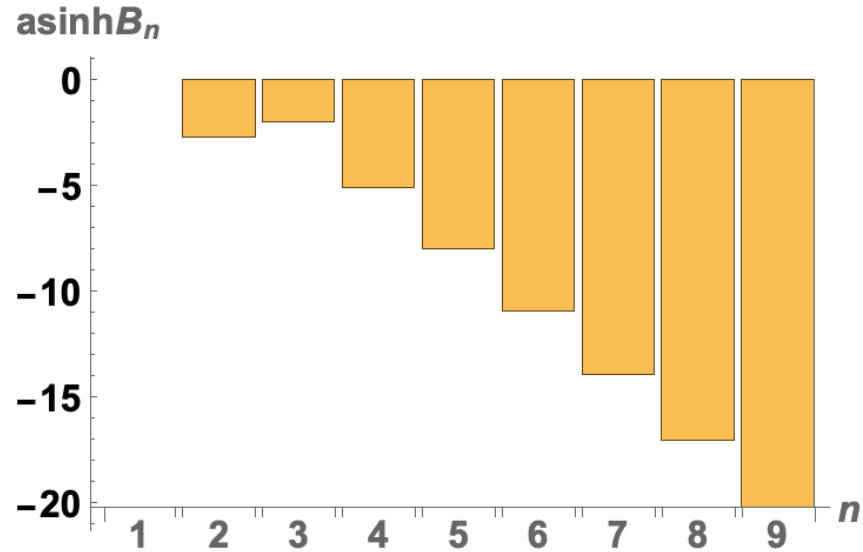

Activity series

All positive, growing exponentially

Density series

All negative, growing exponentially

Activity-series and density-series coefficients are very different

3D Lennard-Jones, medium temperature ($T = 1.2$)

Activity series

All positive, growing exponentially

Density series

Mixed sign, growing exponentially

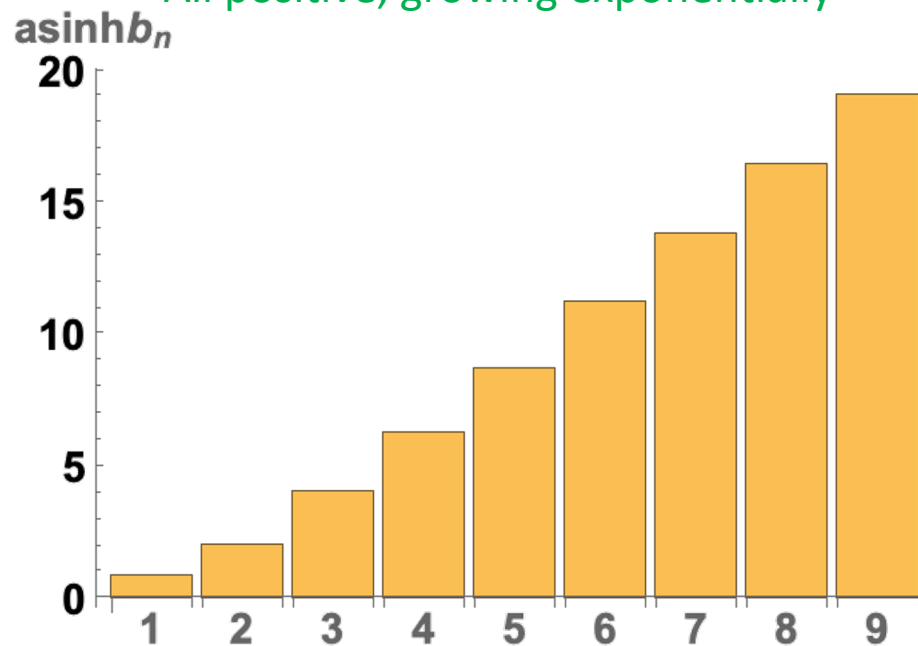

Activity-series and density-series coefficients are very different

3D Lennard-Jones, medium temperature ($T = 1.2$)

Activity series

All positive, growing exponentially

Density series

Mixed sign, growing exponentially

Higher temperatures become qualitatively similar to HR

There is a concise, exact* relation between the N -molecule canonical partition function and the b_n coefficients, $n \leq N$

$$Z(N, V) = \sum_{\substack{\{m_j\} \\ \sum_{j=1}^N jm_j = N}} \prod_{j=1}^N \frac{(Vb_j)^{m_j}}{m_j!}$$

Physical meaning

$$Z(5, V) = \begin{array}{c} \boxed{\text{5 dots}} + \boxed{\text{2 dots}} + \boxed{\text{4 dots}} + \boxed{\text{3 dots}} + \boxed{\text{1 dot}} + \boxed{\text{2 dots}} + \boxed{\text{5 dots}} \\ \hline Vb_5 \quad V^2b_2b_3 \quad V^2b_1b_4 \quad V^3b_1b_2^2 \quad V^3b_1^2b_3 \quad V^4b_1^3b_2 \quad V^5b_1^5 \end{array}$$

b_j given by the reducible (singly-connected) integrals

* $b_j = b_j(V)$

In principle, the b_n are volume dependent, and this is distinct from density dependent

$$Z(N, V) = \sum_{\substack{\{m_j\} \\ \sum_{j=1}^N jm_j = N}} \prod_{j=1}^N \frac{(Vb_j)^{m_j}}{m_j!}$$

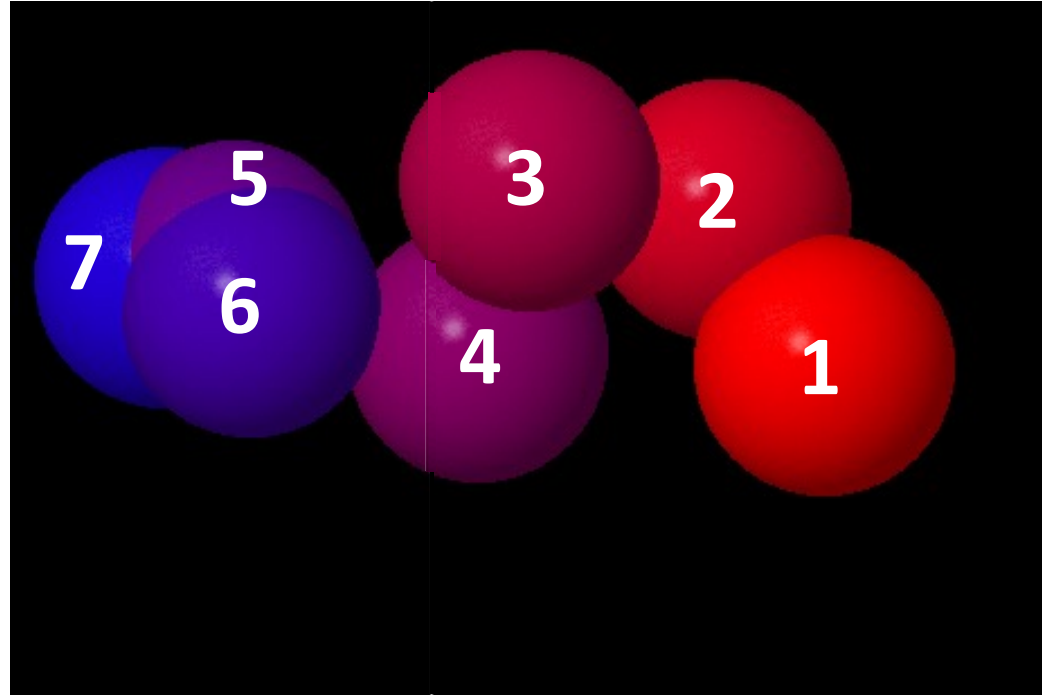

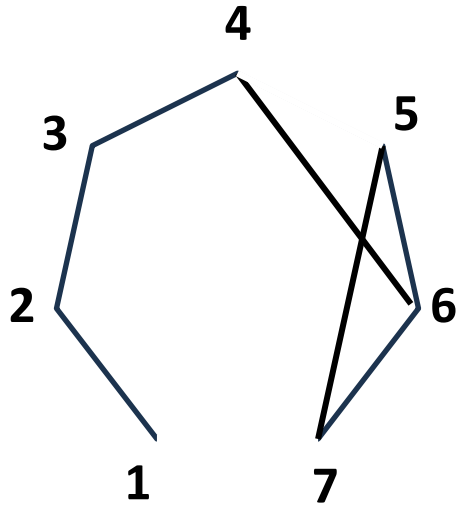

Physical meaning

$$Z(5, V) = \begin{array}{c} \begin{array}{ccccccc} \begin{array}{|c|} \hline \bullet \bullet \bullet \\ \hline \end{array} & + & \begin{array}{|c|} \hline \bullet \bullet \\ \hline \end{array} & + & \begin{array}{|c|} \hline \bullet \bullet \bullet \\ \hline \end{array} & + & \begin{array}{|c|} \hline \bullet \bullet \\ \hline \end{array} & + & \begin{array}{|c|} \hline \bullet \bullet \bullet \\ \hline \end{array} & + & \begin{array}{|c|} \hline \bullet \bullet \bullet \\ \hline \end{array} & + & \begin{array}{|c|} \hline \bullet \bullet \bullet \\ \hline \end{array} & + & \begin{array}{|c|} \hline \bullet \bullet \bullet \\ \hline \end{array} \\ \hline Vb_5 & & V^2b_2b_3 & & V^2b_1b_4 & & V^3b_1b_2^2 & & V^3b_1^2b_3 & & V^4b_1^3b_2 & & V^5b_1^5 \end{array} \end{array}$$

$$Z(4, V) = \begin{array}{c} \begin{array}{ccccc} \begin{array}{|c|} \hline \bullet \bullet \bullet \\ \hline \end{array} & + & \begin{array}{|c|} \hline \bullet \bullet \\ \hline \end{array} & + & \begin{array}{|c|} \hline \bullet \bullet \\ \hline \end{array} & + & \begin{array}{|c|} \hline \bullet \bullet \\ \hline \end{array} & + & \begin{array}{|c|} \hline \bullet \bullet \\ \hline \end{array} & + & \begin{array}{|c|} \hline \bullet \bullet \\ \hline \end{array} \\ \hline Vb_4 & & V^2b_1b_3 & & V^2b_2^2 & & V^3b_1^2b_2 & & V^4b_1^4 \end{array} \end{array}$$

Volume-dependent virial coefficients

This configuration is not doubly connected. Contributes to b_7 , but not to B_7

Volume-dependent virial coefficients

With PBC, the same configuration *is* doubly connected. It contributes to b_7 and B_7

Some Features of PBC Volume-Dependent Virial Coefficients

- Volume dependence arises primarily for graphs that can connect an atom to one of its images.
- Can also arise at box lengths smaller than range of pair interaction
- For volumes larger than this, a graph will not be volume dependent
- Volume dependence arises only in doubly-connected graphs, or doubly-connected parts of singly-connected graphs

← This is volume dependent to larger volumes than this →

...which is about the same as this →

The $N, V \rightarrow \infty$ limiting process underlying the VEOS is fraught, even without the issue of coefficient volume dependence

A term like this arises in the development of the activity series

$$G(x, V, N_m) \equiv \frac{1}{V} \ln \sum_{n=0}^{N_m} \frac{(Vx)^n}{n!} \quad N_m \rightarrow \infty$$

Its behavior differs markedly depending on how the simultaneous limit is performed

Activity-series b_n go to zero slowly with decreasing volume

1D hard-rod model (analytic results)

Exact (solid) and empirical fit (dashed)

$$Z(N, V) = \sum_{\{m_j\}} \prod_{j=1}^N \frac{(Vb_j)^{m_j}}{m_j!}$$

$\sum_{j=1}^N jm_j = N$

□• □• □• □• □•

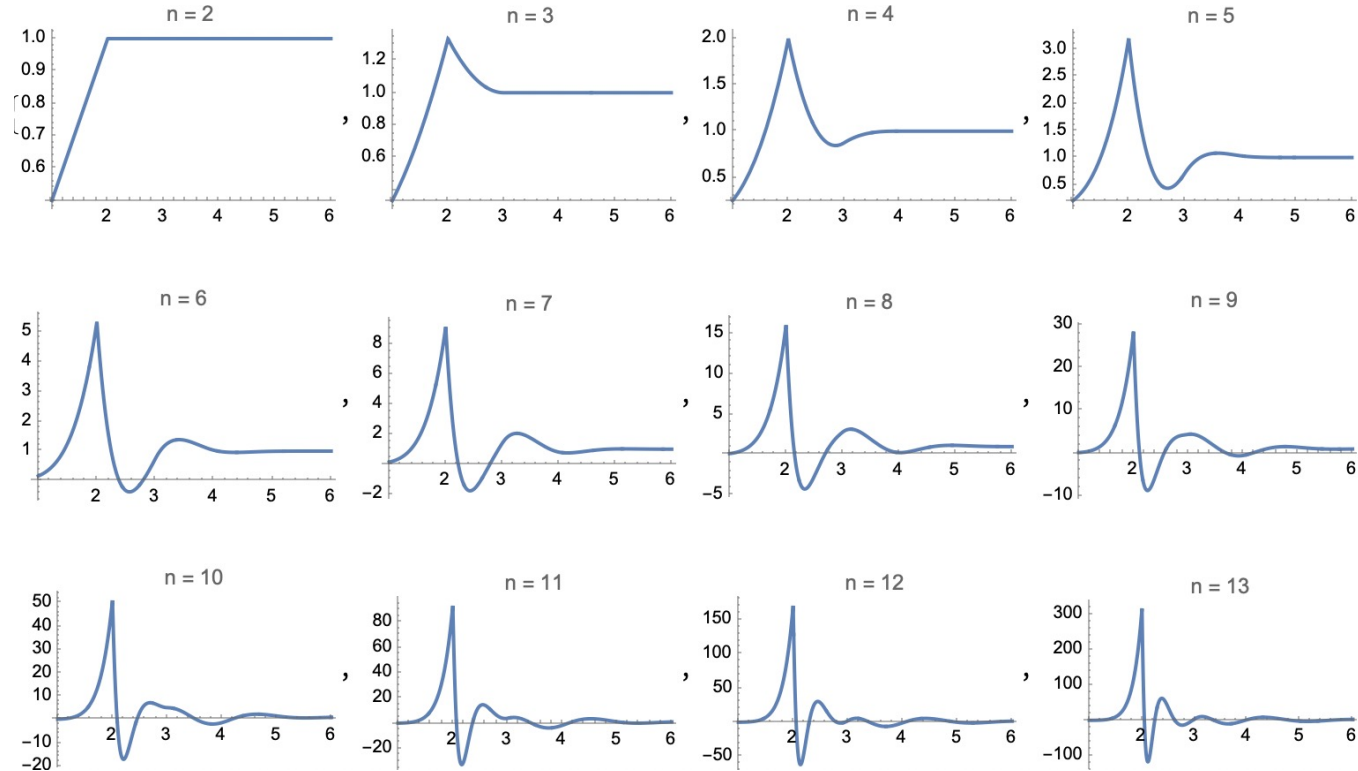

= 0 for small V

$$b_n^{\text{fit}}(V) = \frac{3V^6}{3V^6 + n^3d^6} b_n$$

$$V_{1/2} \sim \sqrt{n}$$

Density-series B_n have more complicated behavior

1D hard-rod model

Finite size makes B_n much more negative at lower T

Lennard-Jones model

$T = 0.8$

$T = 1.2$

Activity-series coefficients are a bit simpler

Lennard-Jones model

Volume dependence helps VEOS to detect condensation

Volume-independent, $T = 0.8$

Volume dependence helps VEOS to detect condensation

Volume-dependent, $T = 0.8$, $L = 3$

We can attempt extrapolation to infinite n to find condensation

$T = 0.6$

$T = 0.8$

PBC box length, L

— 7.

$T = 1.$

$T = 1.2$

In summary, volume dependence of virial coefficients is an unexplored element of basic statistical mechanics

The thermodynamic limiting process for the formalism needs another look

$$\begin{aligned}
 j=1 & \left(1 + \frac{Vb_1z}{1!} + \frac{[Vb_1z]^2/2!}{2!} + \frac{[Vb_1z]^3/3!}{3!} + \frac{[Vb_1z]^4/4!}{4!} + \dots \right) \\
 j=2 & \times \left(1 + \frac{Vb_2z^2}{1!} + \frac{[Vb_2z^2]^2/2!}{2!} + \frac{[Vb_2z^2]^3/3!}{3!} + \frac{[Vb_2z^2]^4/4!}{4!} + \dots \right) \\
 j=3 & \times \left(1 + \frac{Vb_3z^3}{1!} + \frac{[Vb_3z^3]^2/2!}{2!} + \frac{[Vb_3z^3]^3/3!}{3!} + \frac{[Vb_3z^3]^4/4!}{4!} + \dots \right) \\
 j=4 & \times \left(1 + \frac{Vb_4z^4}{1!} + \frac{[Vb_4z^4]^2/2!}{2!} + \frac{[Vb_4z^4]^3/3!}{3!} + \frac{[Vb_4z^4]^4/4!}{4!} + \dots \right) \\
 & \dots
 \end{aligned}$$

Some regularities are observed in the volume dependence of the coefficients, but too early to tell if it will be persistent or useful

In other work, we explored asymptotic methods to treat the framework, but find extreme difficulty with cancellation of large numbers
